Shaun McGrath Administrator Region 8 U.S. Environmental Protection Agency 1595 Wynkoop Street Denver, CO 80202-1129

Re: Wyoming Department of Environmental Quality Designation Recommendation for Carbon County, Wyoming

Dear Administrator McGrath,

This letter responds to Janet McCabe's (U. S. Environmental Protection Agency (EPA) Acting Assistant Administrator) March 20, 2015 letter to Director Todd Parfitt (Wyoming Department of Environmental Quality (DEQ)) regarding attainment designations for the 2010 1-hour sulfur dioxide (SO<sub>2</sub>) National Ambient Air Quality Standard. This recommendation meets the extended due date of November 2, 2015.

The March 2, 2015 court order directs attainment in three rounds: round one completion date July 2, 2016; round two completion date December 31, 2017; and round three completion date December 31, 2020. Sinclair Wyoming Refining Company's (SWRC) SO<sub>2</sub> air quality monitor recorded a violation of the 2010 SO<sub>2</sub> NAAQS between calendar years 2012 and 2014 in Carbon County. This resulted in Carbon County's inclusion as an area subject to round one designation.

The DEQ's Air Quality Division (AQD) has conducted extensive evaluations of the SWRC  $SO_2$  air quality monitor (AQS ID number 56-007-0852) and surrounding areas. These evaluations are the basis of this designation recommendation. The DEQ-AQD also received modeling from SWRC to assist with the decision. SWRC's modeling was not conducted in accordance with the SO<sub>2</sub> Modeling Technical Assistance Document and was not considered by the DEQ-AQD (supporting document attached).

The DEQ-AQD considered the information in the technical support document and determined available information was inconclusive (due to location of the SWRC SO<sub>2</sub> air quality monitor and the dispersion modeling evaluation). The DEQ-AQD recommends that Carbon County remain unclassified at this time.

Shaun McGrath Administrator Region 8 October 27, 2015 RE: Wyoming Department of Environmental Quality Designation Recommendation for Carbon County, Wyoming Page 2

The DEQ-AQD will work with the EPA (in accordance with 40 CFR 51.1200) to identify SWRC as a stationary source subject to further air quality characterization (SO<sub>2</sub> Data Requirements Rule). The DEQ-AQD has decided to include SWRC in round three of designations – requiring SWRC to conduct additional ambient SO<sub>2</sub> monitoring. This additional monitoring data will be used for the final designation due December 31, 2020.

The DEQ-AQD is pursuing an enforcement action for violation of permit conditions related to ambient air monitors against SWRC. The proposed order will require Sinclair to modify its permitted ambient boundary and to install a monitor in the Town of Sinclair. The DEQ-AQD will coordinate with the EPA and SWRC on a monitoring network in anticipation of the December 31, 2020 designation.

I look forward to working with the EPA finalize an attainment designation for Carbon County, Wyoming.

Sincerely,

141 1

Matthew H. Mead Governor

This air dispersion modeling report was prepared in support of the Wyoming Department of Environmental Quality (WDEQ), Air Quality Division's (AQD) full evaluation performed to determine an appropriate designation for Carbon County, Wyoming for the 2010 1-hour sulfur dioxide (SO<sub>2</sub>) National Ambient Air Quality Standard (NAAQS). This evaluation was prepared in response to Acting Assistant United States Environmental Protection Agency (EPA) Administrator Janet McCabe's letter dated March 20, 2015 to WDEQ Director Todd Parfitt. The WDEQ-AQD conducted this modeling evaluation to inform the designation recommendation.

The WDEQ-AQD contracted with SLR International Corporation (SLR) to conduct the modeling and prepare this report. The modeling methodology was developed in consultation with the WDEQ-AQD to capture the actual Sinclair Wyoming Refining Company (SWRC) operating conditions during the period from 2012 to 2014, to the extent possible, based on available information and data. The air quality modeling was conducted in accordance with guidance provided by the EPA as outlined in the following documents:

- SO<sub>2</sub> NAAQS Designations Modeling Technical Assistance Document (Modeling TAD; EPA 2013).
- Guideline on Air Quality Models [published as 40 CFR 51, Appendix W] (Modeling Guideline; EPA 2005).

SLR used the EPA- and WDEQ-AQD-approved dispersion model and methods described in the above reference documents to perform the modeling analysis.

### 1.1 DOCUMENT ORGANIZATION

This document is organized into four chapters. Chapter 2 provides an overview of the dispersion modeling procedures and inputs. Chapter 3 presents the results and conclusions of the dispersion modeling analysis. Chapter 4 contains a list of references.

### 2. DISPERSION MODELING PROCEDURES AND INPUTS

### 2.1 MODEL SELECTION

Selection of the appropriate dispersion model for use in the analysis was based on the available meteorological input data, the physical characteristics of the sources that are to be simulated, the land use designation in the vicinity of the facility, the complexity of the nearby terrain, and applicable EPA guidance to be used for the 2010 1-hour SO<sub>2</sub> NAAQS designations.

SLR used the current version of the EPA-approved American Meteorological Society/EPA Regulatory Model (AERMOD) modeling system in accordance with the Modeling TAD and the Modeling Guideline. AERMOD is recommended for use in 2010 1-hour SO<sub>2</sub> NAAQS designations when modeling multi-source emissions, and can account for plume downwash, stack tip downwash, and point, area, and volume sources (EPA 2015a; 2013; 2005; and 2004).

Current version numbers of the AERMOD model and pre-processors that were used include:

- AERMAP Version 11103;
- AERSURFACE Version 13016;
- AERMINUTE Version 14337;
- AERMET Version 15181; and
- AERMOD Version 15181.

### 2.2 MODEL INPUT OPTIONS

Model input options were set to their regulatory default values.

#### 2.3 PLUME DOWNWASH

The effects of plume downwash were considered for all SWRC sources. Direction-specific building dimensions were calculated using the current version of the EPA-approved Building Profile Input Program (BPIPPRM Version 04274). Building dimensions were obtained from a BPIPPRM input provided by the WDEQ-AQD used in SWRC's 2014 minor source permit action MD-15648. At the direction of and in consultation with the WDEQ-AQD, additional structures were digitized and included in the downwash analysis in the vicinity of the #3 Tail Gas Treating Unit (TGTU) and #4 TGTU. The additional structures were deemed necessary by the WDEQ-AQD to better characterize plume downwash in the vicinity of these sources.

Actual SWRC stack heights, as provided by the WDEQ-AQD from previous permit modeling, were used for the modeling analysis. The base elevations of all SWRC structures and stacks were obtained from digital elevation data. A description of the digital elevation dataset data is provided in Section 2.8. A simplified plot plan of the SWRC facility, showing the location of

all structures and emission units (EUs) used in the plume downwash calculations, is provided in Figure 2-1.

The effects of plume downwash were not considered for off-site sources because of the very low emissions [ $\leq 0.1$  pound per hour (lb/hr) of SO<sub>2</sub> at each off-site facility] and the relatively large distance from SWRC [between 9.3 and 12 kilometers (km) from SWRC]. Emissions from the off-site sources are not expected to cause a significant impact, regardless of whether or not there is downwash included in the modeling.

#### 2.4 METEOROLOGICAL DATA PROCESSING

Hourly meteorological data used for air quality modeling must be spatially and climatologically representative of the area of interest. For attainment designation purposes, the Modeling TAD requires a three year dataset of representative meteorological data, preferably concurrent with actual emissions data. Required surface meteorological data inputs to the AERMOD meteorological processor (AERMET) include, at minimum, hourly observations of wind speed, wind direction, temperature, lateral turbulence, and cloud cover (or solar radiation and low-level vertical temperature difference data in lieu of cloud cover). The meteorological processor also requires morning upper air sounding data from a representative NWS station.

The hourly meteorological data used for the air quality modeling analysis was generated from the following input datasets for calendar years 2012 through 2014:

- The site-specific, 30-m meteorological tower located at the SWRC facility;
- The 1-minute Automated Surface Observing System (ASOS) wind speed and wind direction data reported at the Rawlins airport; and
- The upper air sounding meteorological data collected at Riverton, Wyoming.

#### 2.4.1 SWRC SITE-SPECIFIC DATA

SWRC operates a site-specific, 30-m meteorological monitoring tower located on the northwest corner of the SWRC property. The site-specific data has been used in air quality impact assessments to support construction permit applications using the AERMOD dispersion model. The data are well-suited for AERMOD simulations using concurrent hourly emissions data, which are described later in this report.

The meteorological parameters that were processed for use in the dispersion modeling analysis are:

• 10- and 30-m horizontal meter wind speed, wind direction, and wind direction standard deviation ( $\sigma_{\theta}$ );

Figure 2-1 SWRC Structures and Stacks Used in the Downwash Analysis

- 10- and 30-m vertical wind speed standard deviation ( $\sigma_w$ );
- 2-, 10-, and 30-m ambient temperature;
- 10-2 m ambient temperature difference;
- Total solar radiation; and
- Barometric pressure.

The validated meteorological data were provided by the WQEQ-AQD in Excel format. The validated data were prepared for input to AERMET as follows:

- Original missing data flags (-6999) in the Excel file were set to the AERMET default missing data flags for each parameter; and
- Vertical wind speed standard deviation values less than 0.1 m/s were set to missing<sup>1</sup>.

The quarterly valid data capture for each meteorological parameter (prior to setting  $\sigma_w$  values less than 0.1 m/s to missing) was greater than 98 percent for the three-year period, with the majority of the parameters exceeding 99 percent by quarter.

Figure 2-2 and Figure 2-3 show wind roses for the SWRC 10- and 30-m levels, respectively, for the 2012-2014 period. Both wind roses show predominant winds from the west-southwesterly direction, with secondary maxima from the westerly and southwesterly directions.

Validated SWRC meteorological monitoring data were exported from Excel for use in AERMET. The AERMET processing procedure is described in detail below. A copy of the validated SWRC meteorological dataset that was used for the modeling analysis, along with data processing spreadsheets and meteorological preprocessor input/output files are provided in Appendix A.

#### 2.4.2 NATIONAL WEATHER SERVICE (NWS) SURFACE DATA

Per the WDEQ-AQD's request, 1-minute ASOS wind data from the Rawlins NWS airport site was used to substitute any missing wind data from the SWRC site-specific dataset. The data was obtained from the National Climatic Data Center's (NCDC) FTP site for the years 2012-2014<sup>2</sup>. The 1-minute ASOS data capture at Rawlins was generally good, except data from June through December 2013 was unavailable.

<sup>&</sup>lt;sup>1</sup> According to information provided by EPA's AERMOD Implementation Group (Roger Brode), in the absence of observed sigma-w data, the sigma-w profile is calculated in AERMOD based on the boundary-layer parameters, w\* and u\*. A problem can occur if there is an inconsistent observed sigma-w value that causes an inconsistency between the observed sigma-w values and the calculated w\* value. Such an inconsistency between w\* and observed sigma-w can result in extremely large and unrealistic values of the skewness in convective conditions, which is proportional to (w\*/sigma-w)<sup>3</sup>. This can lead to anomalous plume height and sigma-z values for the updraft and downdraft portions of the direct plume in AERMOD. According to Brode, there is no simple solution to the problem without incorporating a feedback loop between the measured sigma-w and the calculation of w\*, which is not part of the current AERMOD model. He suggests that users should avoid inputs of anomalously low (especially below instrument threshold) input values of sigma-w to AERMOD. Setting input values of ENSR Regarding the Use of Concurrent Meteorological Observations for AERMET Processing [Modeling Protocol for the Granite Fox Power Project, Submitted by ENSR to the Nevada Division of Environmental Protection Bureau of Air Pollution Control]. September 1, 2005).

<sup>&</sup>lt;sup>2</sup> <u>ftp://ftp.ncdc.noaa.gov/pub/data/asos-onemin/</u>

Final\_Modeling\_Report\_102015.docx

#### Figure 2-2 10-meter SWRC Wind Rose

#### Figure 2-3 30-meter SWRC Wind Rose

The 1-minute ASOS data was processed using the AERMINUTE program to create a file of hourly averages of wind speed and wind direction for the Rawlins data set. Figure 2-4 shows the wind rose for the hourly averaged AERMINUTE output, which generally matches the wind roses for the SWRC site-specific data.

Missing SWRC wind data was substituted with the AERMINUTE output in stage 2 of the AERMET processing. The SWRC wind data was substituted with Rawlins wind data by AERMET as summarized below:

- 22 times in year 2012;
- 10 times in year 2013; and
- 38 times in year 2014.

#### 2.4.3 NWS UPPER AIR DATA

The temperature structure of the atmosphere prior to sunrise is required by AERMET to estimate the growth of the convective boundary layer for the day. AERMET uses the 1200 Greenwich Mean Time (GMT) upper air sounding from the nearest NWS upper air observing station for this purpose. Without the 12Z sounding, AERMET will set the daytime convective boundary layer parameters to missing for that day, and AERMOD will flag these hours as missing and not perform dispersion calculations. The nearest upper air site to the SWRC facility is located in Riverton, Wyoming, approximately 181 km northwest of SWRC. The upper air data for this site were obtained from the Forecast Systems Laboratory (FSL)/NCDC Radiosonde Data Archive<sup>3</sup> and provided as input to AERMET.

During the AERMET processing, it was determined that thirteen 12Z soundings were missing during the three-year period of interest: nine were missing in 2012; two were missing in 2013, and two were missing in 2014. At the direction of the WDEQ-AQD, and in order to construct the most complete dataset possible and retain valid site-specific surface meteorological data in the modeling analysis, the missing soundings were filled using either the prior day's sounding or the subsequent day's sounding from Riverton.

Since AERMET uses the vertical temperature data from the sounding up to 5,000 m above ground level, an analysis of archived 500 millibar (mb) weather maps<sup>4</sup> was conducted to find the most appropriate day to use for the substitution. Since the vertical temperature profile is the parameter used by AERMET, the analysis focused on the 1,000-500 mb thicknesses<sup>5</sup>, but also qualitatively considered wind flow, wind speed, and proximity of low/high pressure systems. It is recognized that the selection of the appropriate day to use as a substitute is subjective; therefore an additional analysis was conducted in which AERMET/AERMOD were run two ways for a single day on January 27, 2012: 1) using the 12Z sounding from the day prior to the missing day, and 2) using the 12Z sounding from the day after the missing day. Between the two runs, the AERMET surface files do have somewhat different

<sup>&</sup>lt;sup>3</sup> <u>http://www.esrl.noaa.gov/raobs/</u>

<sup>&</sup>lt;sup>4</sup> <u>http://archive.atmos.colostate.edu/data/misc/QHTA11/</u>

<sup>&</sup>lt;sup>5</sup> The 1000-500 mb thickness is directly related to the temperature of the column.

#### Figure 2-4 10-meter Rawlins Wind Rose Generated from 1-Minute ASOS Data

convective parameters; however the resulting maximum hourly concentrations for the two runs were identical<sup>6</sup>. A brief discussion of the selected substitution days along with the archived maps are provided in Appendix B.

#### 2.4.4 SURFACE CHARACTERISTICS

Processing of the meteorological data requires assigning appropriate surface characteristics including surface roughness length ( $z_0$ ), Bowen Ratio ( $B_0$ ), and albedo (r). Surface characteristics were assigned following guidance provided in the current version of the AERMOD Implementation Guide (AIG; EPA 2015b).

The AIG recommends that the surface characteristics be determined based on digitized land cover data. The EPA has developed the AERSURFACE processor that can be used to determine site characteristics based on digitized land cover data in accordance with the recommendations from the AIG. AERSURFACE incorporates look-up tables of representative surface characteristic values by land cover category and seasonal category.

The AERSURFACE processor was used to obtain the surface characteristics for input to stage 3 of AERMET. The current version of AERSURFACE was used with land cover data from the United States Geological Survey (USGS) National Land Cover Data 1992 archives (NLCD92). The NLCD92 archive provides data at a spatial resolution of 30 m based on a 21-category classification scheme applied over the continental United States.

AERSURFACE was used to calculate surface characteristics for twelve 30-degree sectors for two meteorological sites: the SWRC site-specific tower and Rawlins airport.

The latitude and longitude<sup>7</sup> of these stations are:

- SWRC tower: 41.78491 north latitude, 107.1152 west longitude; and
- Rawlins tower: 41.7994 north latitude, 107.2064 west longitude.

#### 2.4.4.1 Seasonal Classification

In AERSURFACE, the various land cover categories are linked to a set of seasonal surface characteristics for each land cover category. As such, AERSURFACE requires specification of the seasonal category for each month of the year. The following five seasonal categories are offered by AERSURFACE:

- Late autumn after frost and harvest, or winter with no snow (with default months: December, January and February);
- Winter with continuous snow on ground (with default months: December, January and February);

<sup>&</sup>lt;sup>6</sup> AERMOD was run for 24 hours using the modeling files WDEQ-AQD provided from minor source permit action MD-15648. When paired in space and time, the top 20 1-hour impacts between the two runs were identical.

<sup>&</sup>lt;sup>7</sup> Coordinates in North American Datum 1983 (NAD83).

- Transitional spring with partial green coverage or short annuals (with default months: March, April and May);
- Midsummer with lush vegetation (with default months: June, July and August); and
- Autumn with un-harvested cropland; (with default months: September, October and November).

Following WDEQ-AQD guidance, each month was assigned to its default season unless evidence of snow cover would change the default season to winter with snow. In addition, in some years the transition months of November and March may have continuous snow cover and would be classified as winter with snow. For each winter month and the adjacent transitional months, snow cover was evaluated to determine if the month should be classified as winter with no snow.

The availability of snow cover data from nearby stations listed in the Global Historical Climatology Network (GHCN)<sup>8</sup> was evaluated. Only one site, Sinclair 0.1 N (WY-CR-9), which is a Community Collaborative Rain, Hail & Snow Network (CoCoRaHS) station, had consistent data capture for the snow depth field for the years 2012-2014. The Rawlins airport has an archive of daily snow depth based on approximately 50 years of data<sup>9</sup>, but data collection ceased in the year 2000. Analysis of this archive shows that the Rawlins airport (approximately 8 km west-northwest of SWRC) typically has snow depth greater than 1 inch from November 20 through March 12.

Using these data sets, each month was evaluated to determine if greater than 50 percent of the days within that month had snow depth more than 1 inch. A month that had greater than 50 percent of the days with snow depth more than 1 inch was classified as winter with snow; otherwise it was classified as winter with no snow (i.e., for the months December, January, or February) or its default season (e.g., for the transitional months of November or March).

Since the CoCoRaHS program is supported by volunteers, there may be periods of missing data. Therefore, the following procedure was implemented to evaluate all winter and transition months:

- 1. If the WY-CR-9 site had data capture such that >50 percent of the days in a month have snow depth ≥1 inch, classify that month as winter with snow.
- 2. If the WY-CR-9 site had data capture such that >50 percent of the days in a month do not have snow depth ≥1 inch, classify that month as winter with no snow or the default season.
- 3. If the WY-CR-9 site did not have 50 percent data capture (i.e., less than half the month had any observations), then classify winter months as winter with snow based on Rawlins snow depth climatology, and classify all other months as their default season.

<sup>&</sup>lt;sup>8</sup> <u>ftp://ftp.ncdc.noaa.gov/pub/data/ghcn/daily/by\_year/</u>

<sup>&</sup>lt;sup>9</sup> <u>http://www.wrcc.dri.edu/cgi-bin/cliMAIN.pl?wy7533</u>

Final\_Modeling\_Report\_102015.docx

For the period of interest, this procedure results in all December, January, and February months to be classified as winter with snow except for January 2012, which had enough observations to support winter with no snow. All transition months were classified as their default seasons. The monthly seasonal determinations for each year are provided in Table 2-1 through Table 2-3.

#### 2.4.4.2 Surface Moisture Determination

The surface moisture condition (average, dry, or wet) for each month was determined by comparing the observed precipitation for each month within the period of interest (years 2012-2014) to the 30 year climatological record for that month. "Wet" conditions were selected if monthly precipitation was in the upper 30<sup>th</sup> percentile of the climate record, "dry" conditions if precipitation was in the lower 30<sup>th</sup> percentile of the climate record, and "average" conditions if precipitation was in the middle 40<sup>th</sup> percentile of the climate record. The 30 year climatological record for each month was based on the Rawlins airport data from 1980-2010. The observed precipitation for the 2012-2014 period was also obtained from the Rawlins airport. The monthly surface moisture determinations for each year are provided in Table 2-1 through Table 2-3.

#### 2.4.4.3 AERSURFACE Processing

The AERSURFACE processor was run for both the SWRC and Rawlins meteorological tower locations using the above inputs and seasonal definitions. Due to limitations in the code, only one moisture classification, and one arid or non-arid classification, per year can be input to AERSURFACE. Therefore, AERSURFACE was run six separate times with the following settings: 1) arid and dry moisture; 2) arid and wet moisture; 3) arid and average moisture; 4) non-arid and dry moisture; 5) non-arid and wet moisture; and 6) non-arid and average moisture. All winter with snow months were run as non-arid (based on the AERSURFACE definition) and all months with no snow were run as arid (based on an annual precipitation total of around 9 inches, and per the WDEQ-AQD's direction). Based on the monthly seasonal and moisture classifications listed in Table 2-1 through Table 2-3, the appropriate geophysical parameters were used for each month of the 2012-2014 period as input into stage 3 of AERMET.

Figure 2-5 illustrates the NLCD92 cover data overlaid with the AERSURFACE land cover output for the Bowen ratio and albedo domains. The domain for the surface roughness (1-km radius surrounding each meteorological tower) is contained within the larger Bowen ratio and albedo domains. Review of this figure indicates the input/output land cover is properly matched, aligned, and consistent with expectations.

Table 2-1	Year 2012 Sea	sonal and Moistur	e Determinations
-----------	---------------	-------------------	------------------

Month	Maximum snow depth <sup>1</sup>	Average snow depth <sup>1</sup>	Days with Snow on Ground <sup>1,2</sup>	Days with Missing Snow Data	Seasonal Classification <sup>2</sup>	Justification for Seasonal Classification	Soil Moisture Classification <sup>3</sup>	Aridity Classification
	(in)	(in)

#### 2.4.5 AERMET PROCESSING

The SWRC site-specific surface meteorological data (as supplemented with 1-minute ASOS wind data from Rawlins where needed), Riverton upper air data, and surface characteristics were processed using the latest version of the AERMET processor to generate AERMOD-ready surface and profile files. Stage 3 of AERMET was run for each individual year to retain the seasonal and moisture determinations for each year. The individual AERMET generated files were combined into single surface and profile files to allow the AERMOD dispersion model to output the appropriate modeled design value of the 1-hour SO<sub>2</sub> concentrations for comparison against the 1-hour SO<sub>2</sub> NAAQS.

#### MODELED EMISSION INVENTORY 2.5

#### 2.5.1 SWRC EMISSION UNITS

The SWRC modeled emission inventory was developed using several sources of information and data to capture the SWRC operating conditions during the period from 2012 to 2014. The modeled inventory was developed from the following:

- The primary sources of hourly actual SO<sub>2</sub> emissions data were obtained from • SWRC's continuous emission monitoring systems (CEMS) for specific emission units (EU) described later in this section;
- Root Cause Failure Analysis (RCFA) reports that were prepared as required by the • May 8, 2008 Consent Decree (Consent Decree) between the United States of America and SWRC for specific EUs described later in this section;
- Annual emission inventory reports submitted to the WDEQ-AQD required by SWRC's Operating Permit; and
- Emission rates and stack parameters from the modeling files associated with SWRC's MD-15648, which 2014 minor source permit action generally reflect Federally-enforceable permit limits for the EUs.

During the period from 2012 through 2014, SWRC EUs experienced upset conditions that were documented in RCFA reports submitted to the EPA, which included information for the following EUs: North Flare, South Flare, Emergency Ground Flare, #1 TGTU Bypass Stack<sup>10</sup>, #3 TGTU, and the #4 TGTU. For these reported events, SWRC provided emission estimates based on event-specific information that they considered more accurate than the CEMS data during the upset events. Specifically, SWRC provided a statement in the TGTU RCFA reports, that SWRC's engineering calculations were reported "...in lieu of the CEMS reading, which was inaccurate...<sup>11</sup>".

Sulfur dioxide concentrations from the CEMS during upset conditions may or may not have exceeded the upper range of the CEMS. Therefore, in order to characterize the actual hourly SO<sub>2</sub> emissions from the sources with CEMS/RCFA data for upset conditions, SLR

<sup>&</sup>lt;sup>10</sup> The #1 TGTU bypass is a bypass to the #1 TGTU stack. This bypass also serves the #1 sulfur recover unit (SRU) and #2 SRU. <sup>11</sup> This statement was included in Attachment 2 of each TGTU RCFA report.

Final\_Modeling\_Report\_102015.docx

substituted the CEMS hourly emissions data with the RCFA report hourly emissions data when RCFA data were available. An overview of this substitution procedure and CEMS code handling is provided in this section.

Emission units that did not have CEMS or RCFA report data were modeled at their permitted allowable emission rates and source release parameters shown in Appendix C. The permitted information was also used for specific EUs during periods where there was no CEMS/RCFA data available for those EUs, as described in this section.

#### 2.5.1.1 TGTU CEMS Code Data Processing

Hourly actual emissions were prepared for the following sources that have a CEMS:

- North Flare;
- South Flare;
- #1 TGTU;
- #1 TGTU Bypass Stack;
- #3 TGTU;
- #4 TGTU; and
- Fluid Catalytic Cracking Unit (FCCU).

The CEMS data required filtering and processing prior to being used to generate the AERMOD hourly emission files described later in this section. The steps taken to prepare the CEMS data for input to AERMOD are summarized below.

#### <u>#1 TGTU From 1/1/12 – 9/30/12 (SWRC's Perillon CEM System):</u>

There were no codes available in the Perillon CEMS output provided by SWRC. Therefore, for hours with available SO<sub>2</sub> concentrations, SLR calculated the lb/hr SO<sub>2</sub> emission rates, in consultation with the WDEQ-AQD. For hours with valid CEMS flow rates, SLR calculated the actual flow rate [actual cubic feet per hour (acf/hr)] using the CEMS dry standard flow rate, previously modeled exhaust temperature (because there is no temperature data in this CEMS data), and pressure/moisture provided in the "readme" tab of the CEMS spreadsheet provided by SWRC.

The CEMS time stamps were in Mountain Standard Time (MST) and Mountain Daylight Savings Time, which required special processing to convert all times to MST for input to the AERMOD hourly emission files. The hours were assumed to be hour beginning (e.g., hour 0100 is the average from 0100 – 0159). There were significant periods of missing records from March 12, 2012 through April 4, 2012, and from August 8, 2012 through September 30, 2012. These missing hours were assumed to have no SO<sub>2</sub> emissions.

#### All TGTUs and FCCU (SWRC's CeDAR CEM System):

SWRC provided hourly SO<sub>2</sub> concentrations, SO<sub>2</sub> lb/hr emission rates, and exhaust flow rates and temperatures for the #1 TGTU (starting on October 1, 2012) and #3 TGTU, #4 TGTU, and FCCU. All of the time stamps were assumed to be in MST and were assumed to be hour beginning. The following steps were taken to process the CeDAR CEMS data for these units.

The SO<sub>2</sub> concentrations [in parts per million by volume on a dry basis (ppmvd)] and flow rate [in dry standard cubic feet per hour (dscf/hr)] CEMS codes were evaluated to determine if the EU was down (and therefore assumed not to be emitting SO<sub>2</sub>), or if the CEM system alone was down or otherwise reporting invalid readings. According to the "readme" tab in the CEMS spreadsheet provided by SWRC, the codes that identify the EU as being down were <13> and <29>. Each hour was coded by SLR as either "DOWN" (i.e., if codes <13> or <29> were found, the EU was not operating, and therefore emitting 0 lb/hr of SO<sub>2</sub>), or "ND" (indicating no data) if the CEMS data was flagged with a code where no valid data is recorded, in which case, the EU was assumed to be operating but was not monitoring valid emissions or flow rates.

For periods coded as "DOWN", an emission rate of 0 lb/hr of SO<sub>2</sub> was used in the AERMOD hourly emission files. For periods coded with "ND", the previous permitted emission rates and stack parameters were used in the AERMOD hourly emission files.

If RCFA report data were available for a given EU, then the CEMS emission rate was substituted with the total lb/hr  $SO_2$  emission rate calculated by SLR from information contained in each RCFA report as described below. Appendix D contains summaries of the RCFA report data that were included in the modeling.

#### 2.5.1.2 CEMS/RCFA Report Emission Substitutions for TGTUs

The following information in each TGTU RCFA report was reviewed for purposes of preparing hourly emission rates that were used as replacements for the CEMS data:

- The stack from which excess emissions were reported, along with the total pounds of excess SO<sub>2</sub> emitted for the event, both of which are noted on the first page of each report's cover letter.
- The total SO<sub>2</sub> concentrations (in ppmvd) at 0 percent oxygen (O<sub>2</sub>)] provided in Attachment 2 of each RCFA report.

SWRC included lb/hr SO<sub>2</sub> emission rates in the RCFA reports; however, these lb/hr rates represented only the <u>excess</u> SO<sub>2</sub> emissions greater than 250 parts per million (ppm). The emissions required for the modeling analysis is the <u>total</u> SO<sub>2</sub> lb/hr emission rate. The total SO<sub>2</sub> concentration, along with the flow rate and percent oxygen, for each hour in the RCFA reports was used to calculate the total SO<sub>2</sub> lb/hr emission rates.

For times when RCFA emissions data were available for a given TGTU, the calculated RCFA total  $lb/hr SO_2$  emission rate was used in place of that TGTU's CEMS data for the corresponding hours, regardless of the codes that were present in the CEMS data.

#### 2.5.1.3 CEMS/RCFA Report Emission Substitutions for Flares

The following information in each flare RCFA report was reviewed for purposes of preparing hourly emission rates that were used as replacements for the CEMS data:

- Start/end times for each event;
- The average pound per hour (lb/hr) SO<sub>2</sub> emission rate during each event;
- The total SO<sub>2</sub> lb/event emissions; and
- The average flare gas flow rate during each event.

For times when RCFA emissions data were available for a given flare, the reported  $lb/hr SO_2$  emission rate was used in place of that flare's CEMS data for the corresponding hours. If a flaring event lasted less than one hour, then the reported lb/event value was used for the hour in which the emissions occurred.

This procedure was followed for the two candlestick flares (North and South flares). During one of the flaring events (February 4 through February 13, 2014), there were three days (February 6 through February 8) when refinery gases were assumed to be released from the Emergency Ground Flare, based on the event description in the RCFA report. This flare does not have a CEMS and is only used for emergency purposes; therefore, the RCFA emissions from the ground flare were used during February 6 through February 8, with zero emissions occurring for all other days in the 2012-2014 period.

#### 2.5.1.4 AERMOD Hourly Emission File Development

The AERMOD hourly emission files were developed using the available CEMS and RCFA report data, along with emission rates and stack parameters from the modeling files associated with SWRC's 2014 minor source permit action MD-15648. Hourly emission files are used in AERMOD for varying emission rates, stack temperatures, and velocities. Other stack information such as the Universal Transverse Mercator (UTM) locations, base elevations, and diameters are "fixed" in the model and were obtained from the previous modeling files, with updates where appropriate in coordination with the WDEQ-AQD.

The hourly emission files were developed by adding the following information to SWRC's CEMS spreadsheets.

#### TGTUs and FCCU:

• The required AERMOD keywords, model times (hours converted to hour-ending to be consistent with the meteorological data), and the modeled stack ID.

- If RCFA report information was available, the total lb/hr SO<sub>2</sub> emission rates from the RCFA report was input to the hourly emission file, in units of grams per second (g/s). In these cases, the CEMS emission rates were not used.
- If the CEMS data were coded as "DOWN", then 0 g/s was input to the hourly emission file. If the CEMS data coded as "ND", the permitted emission rate was input to the hourly emission file, along with the previous permitted stack parameters.
- For hours with valid CEMS emissions data that were not substituted with RCFA data, the CEMS emission rates and exhaust temperatures were input to the hourly emission file.
- For hours with valid CEMS emissions and flow rates, SLR used the CEMS actual flow rate (acf/hr) and previous modeled stack diameter to calculate the stack velocity in the hourly emission file. If CEMS emissions or flow rate was coded as "ND", then the previous permitted stack velocity was input to the hourly emission file.

#### North and South Flares:

- The required AERMOD keywords, model times (hours converted to hour-ending to be consistent with the meteorological data), and the modeled stack ID.
- If RCFA report information was available, the total lb/hr SO<sub>2</sub> emission rates from the RCFA report was input to the hourly emission file, in units of g/s. In these cases, the CEMS emission rates were not used.
- Since the effective release height and diameter cannot be varied in the AERMOD hourly emission files, these parameters were calculated following EPA's screening procedures (EPA 1995) using each flare's physical stack height and average flare gas heat content obtained from the 2012, 2013, and 2014 annual emission reports. The gas heat contents for each year were applied to the flare gas flow rates during events for each year. The calculated 3-year average effective release heights and diameters were used in the AERMOD input file for the stack height and diameter.
- The flare exhaust temperature and velocity were set to the EPA (1995) default values of 1,273 Kelvin (K) and 20 meters per second (m/s), respectively.

The Emergency Ground Flare was characterized in AERMOD as a volume source, in consultation with the WDEQ-AQD. Since the Emergency Ground Flare only had emissions from February 6 through February 8, 2014, the AERMOD hourly emission file contained RCFA report emissions for this period with zero emissions occurring for all other days in the 2012-2014 period.

#### 2.5.2 OFF-SITE SOURCES

Off-site sources were obtained from SWRC's 2014 minor source permit action MD-15648. The following off-site sources were included in the AERMOD model runs:

- Rostad Mortuary Crematory; and
- Wyoming Department of Corrections

Emissions from these facilities consisted of combustion sources. Figure 2-6 shows the locations of these facilities in relation to the SWRC refinery.

#### 2.6 URBAN SOURCE CLASSIFICATION

An Auer land-use analysis, as described in the Modeling Guideline was conducted to determine the appropriate dispersion coefficients to use in the AERMOD model. Given limited development around the SWRC facility, a qualitative land-use analysis was performed utilizing aerial imagery from Google Earth. Less than 50 percent of the area within a 3 km radius of the SWRC facility could be classified as land use types I1, I2, C1, R2, or R3 [heavy industrial, light/moderate industrial, commercial, compact residential (single family), or compact residential (multi-family), respectively]. Therefore, the URBANOPT keyword in AERMOD was not used.

#### 2.7 AMBIENT AIR BOUNDARY

SWRC's currently permitted modeling ambient boundary was used. A drawing showing the modeled ambient air boundary is provided in Figure 2-7.

#### 2.8 RECEPTOR NETWORK

The receptor grid that was used in SWRC's 2012 PSD major modification permit action MD-12620 was used in the modeling analysis, which was provided by the WDEQ-AQD. Cartesian receptor grids were defined in UTM Zone 13 NAD27 coordinates. The grids were determined to adequately resolve the highest predicted pollutant impacts while at the same time allowing for reasonable execution time. Several nested receptor grids of varying resolution were placed at:

- 50-m resolution along the ambient air boundary.
- 100-m resolution extending to 1 km from the ambient air boundary.
- 250-m resolution from the edge of the 100-m grid extending to 3 km from the ambient air boundary.
- 500-m resolution from the edge of the 250-m grid extending to 10 km from the ambient air boundary.
- 1,000-m resolution extending from the edge of the 500-m grid to 25 km from the ambient air boundary.

Receptor elevation and scale heights were obtained using the AERMAP terrain processor. The digital elevation dataset provided as input to AERMAP was National Elevation Dataset (NED) data at 1/3 arc-second resolution, which is equivalent to approximately 10 m in the project area.

#### Figure 2-6 Modeled Off-Site Source Locations

To obtain the correct hill height scale for each receptor, the digital terrain data file provided to AERMAP included a buffer of approximately 10 km beyond the receptor grid area. In addition, 1:24,000 and 1:250,000 scale maps of the project area were examined to make sure that all significant terrain features at or above a 10 percent slope from each receptor were included in the digital terrain data file(s) provided to AERMAP.

Drawings showing the receptor grids, and contoured receptor elevations overlaid onto topographic maps, are provided in Figure 2-8 through Figure 2-11.

#### 2.9 BACKGROUND CONCENTRATIONS

In addition to including off-site emissions, hourly background concentrations were included in the AERMOD model simulations. Per Section 8.1 of the Modeling TAD, and at the direction of the WDEQ-AQD, background SO<sub>2</sub> concentrations were processed for the WDEQ-AQD's Sinclair Mobile monitor located in the Town of Sinclair [EPA Air Quality System (AQS) ID number 56-007-1000]. The hourly ambient SO<sub>2</sub> concentrations from this monitor were processed in Excel to develop temporally and seasonally-varying background values, excluding periods when emissions from SWRC are expected to impact the monitor (i.e., excluding times when the winds are blowing from SWRC).

While the Modeling Guideline Section 8.2.2b recommends that a 90 degree sector downwind of the emission source may be used to determine the area of impact of that source on a monitor, this recommendation is interpreted to be intended for specific individual point sources of emissions. For this air quality impact assessment, due to the proximity of the ambient monitor to the numerous SWRC emission sources located immediately west of the monitor, arcs were drawn from the location of the ambient monitor for use in determining the wind directions that would be impacted by SWRC emissions.

Figure 2-12 is a map showing these arcs and areas that were considered when developing the background concentrations (i.e., the <u>unshaded</u> areas were considered to not be impacted by SWRC emissions). The wind directions that were included were from 150 degrees through 70 degrees, with all other wind directions (i.e., winds bellowing from SWRC) excluded from the data processing. This approach was directed by the WDEQ-AQD to minimize influences from SWRC on the background concentrations used in AERMOD.

The modeling TAD states that the background can take the form of the NAAQS for the temporally/seasonally-varying processing (i.e., the 3-year average of the 99<sup>th</sup> percentile of the daily maximum 1-hour values). The WDEQ-AQD reviewed the Modeling TAD's recommendation for 3-years of monitored data for background and the use of the 3-year average of the 99<sup>th</sup> percentile values. Since the Sinclair Mobile Monitor has one full year of data, the WDEQ-AQD indicated that using the 2<sup>nd</sup> highest concentrations from the monitor was appropriate.

#### Figure 2-8 Far-Field Receptor Grid

Figure 2-9 Far-Field Receptor AERMAP Elevations

Figure 2-10 Near-Field Receptor Grid

Figure 2-11 Near-Field Receptor AERMAP Elevations

Figure 2-12 Wind Directions Considered for Developing Background SO<sub>2</sub> Concentrations

Based on SLR's review of the WDEQ-AQD's gridded 4-km resolution  $SO_2$  emission inventory, the background concentrations developed for this impact analysis is considered representative of both distant and local, diffuse emission sources in the area. The temporally and seasonally-varying background concentrations used in the AERMOD simulations are provided in Appendix E.

## 3. DISPERSION MODELING RESULTS AND CONCLUSIONS

The results of the modeling analysis indicated that there were no modeled violations of the 1-hour SO<sub>2</sub> NAAQS within the receptor grid developed for areas on and outside of the SWRC permitted modeling ambient air boundary. The maximum modeled 1-hour SO<sub>2</sub> design value concentration predicted by AERMOD was 62.1 parts per billion (ppb) [162.6 micrograms per cubic meter ( $\mu$ g/m<sup>3</sup>)] compared to the NAAQS of 75 ppb (196  $\mu$ g/m<sup>3</sup>). Isopleth maps of the modeled 1-hour SO<sub>2</sub> design value concentrations are provided in Figure 3-1 through Figure 3-3.

Review of Figure 3-1 and Figure 3-2 indicates that the maximum modeled design values occur in the vicinity of SWRC with no elevated design value impacts in the near or far-field of the modeling domain. Figure 3-3 provides a near-field isopleth map of the modeled 1-hour  $SO_2$  design value concentrations in the immediate vicinity of the SWRC stationary source and SWRC  $SO_2$  air quality monitor (AQS ID 56-007-0852). This figure shows a strong  $SO_2$  concentration gradient to the north and northeast of SWRC emission units, and in the area around the SWRC  $SO_2$  air quality monitor.

Based on the refined dispersion modeling results and a comparison of those results to available air quality monitoring data for the same time period, the WDEQ-AQD determined that the modeling evaluation was inconclusive for making an attainment or nonattainment designation for the 2010 1-hour SO<sub>2</sub> NAAQS. As such, the WDEQ-AQD recommends that Carbon County remains designated as unclassifiable at this time.

Copies of all terrain and meteorological processing files, BPIPPRM input and output files, hourly emission and background  $SO_2$  files, and AERMOD model input and output files can be found on the CD-ROM in Appendix A.

# **APPENDIX A**

**CD-ROM with All Processing and Model I/O Files** 

### Final Air Dispersion Modeling Report in Support of the 2010 1-Hour Sulfur Dioxide NAAQS Designation Recommendation

Wyoming Department of Environmental Quality - Air Quality Division 200 West 17th Street Cheyenne, WY 82002

October 20, 2015

This DVD contains model input/output files, and associated inputs and processing data, used in the dispersion modeling to support the WDEQ-AQD's 2010 1-hour sulfur dioxide NAAQS designation recommendation for Carbon County, WY.

The individual file contents for each directory are described below:

#### EXECUTABLES

General Description

This folder contains model and processor PC executables. There are subfolders for each model/processor.

#### AERMAP

General Description

This folder contains input/output files for all AERMAP runs. The first level subfolder (e.g., 100m\_grid, stacks, etc.) indicates the receptor grid and buildings/sources that were processed. All file names are identical for each subfolder and are described below, as applicable for the receptor/building/source processing.

File Name	File Contents
*.inp	AERMAP input file
*.out	AERMAP output file
*.rec	Receptor elevations and height scales extracted by AERMAP
*.sou	Building or source elevations extracted by AERMAP
*.tif	NED terrain data file

#### BPIP

<u>General Description</u> This folder contains BPIP input and output files.

File Name	File Contents
*.inp	BPIP input file
*.out	BPIP output file
*.sum	BPIP summary output file

#### AERSURFACE

General Description

This folder contains input/output files for the 2012-2014 AERSURFACE runs. The years are separated into their own folders. The 'NLCD' folder contains the 1992 NLCD land cover data that was used.

File Name	File Contents
rawl*.inp	6 AERSURFACE input files for the Rawlins site for 6 moisture/aridity classifications (arid/dry;
	arid/average; arid/wet; not arid/dry; not arid/average; not arid/wet)
rawl_stage3.inp	The hand-edited file that combined the AERSURFACE Rawlins output from the above runs, by month
	and classification, into the input for stage3 AERMET processing
raw*.dat	AERSURFACE output files for each of the 6 classifications for the Rawlins site
raw*.log	AERSURFACE log files for each of the 6 classifications for the Rawlins site
sinc*.inp	6 AERSURFACE input files for the Sinclair site for 6 moisture/aridity classifications (arid/dry;
	arid/average; arid/wet; not arid/dry; not arid/average; not arid/wet)
sinc_stage3.inp	The hand-edited file that combined the AERSURFACE Sinclair output from the above runs, by month
	and classification, into the input for stage3 AERMET processing
sin*.dat	AERSURFACE output files for each of the 6 classifications for the Sinclair site
sin*.log	AERSURFACE log files for each of the 6 classifications for the Sinclair site

#### AERMINUTE

<u>General Description</u> This folder contains AERMINUTE input and output files.

File Name	File Contents
*.dat	Various input/output AERMINUTE files
*.inp	AERMINUTE input file
*.log	AERMINUTE log file

#### AERMET

General Description

This folder contains input/output files for the 2012-2014 AERMET runs. Subfolders indicate folders containing upper air data and Sinclair site-specific data. Files not listed below are various output files for the different AERMET stages.

File Name	File Contents
*.inp	AERMET input file

### AERMOD

General Description

This folder contains input/output files for the AERMOD model run. .

<u>File Name</u>	File Contents
*.inp	AERMOD input file
*.out	AERMOD output file
*.plt	Plot files. File name indicates the source group and averaging period
*.dat	AERMOD error file
*.prn	Hourly emission and background SO <sub>2</sub> files

## **APPENDIX B**

Upper Air Sounding Substitution Discussion and Archived 500 mb Maps

### Final Air Dispersion Modeling Report in Support of the 2010 1-Hour Sulfur Dioxide NAAQS Designation Recommendation

Wyoming Department of Environmental Quality - Air Quality Division 200 West 17th Street Cheyenne, WY 82002

October 20, 2015

An analysis was performed to select the most appropriate day to use as a substitute for the days with missing 12Z upper air soundings at Riverton. The table on the nest page lists the following information:

- each day with a missing 12Z sounding for the 2012-2014 period;
- the day selected to use a substitute for the missing day;
- the approximate thickness values for the area of interest; and
- a qualitative discussion about the winds at 500-mb for the days of interest.

The cells highlighted in green indicate that the day was selected to use as a substitute. The cells highlighted in red indicate that the sounding data for that day is missing at Riverton. The graphics following the table are the 500-mb maps used for the analysis.

Missing Day Sub		Substituted W/ith		Map Analysis			Map Analysis	
		Substitu		1000-500 mb Thickness (dm)		(dm)	Winds	
Year	Month	Day	Month	Day	Day Prior	Missing Day	Day After	winds
12	1	27	1	28	558 - 564	546 - 552	552 - 558	Somewhat similar northwest flow; on back side of the same low pressure in Canada
12	3	4	3	5	546	564	564 - 570	Flow is weaker, but similar thickness as missing day
12	3	27	3	28	564	558	564	Similar weak, zonal or southwesterly flow to missing day
12	4	30	5	1	558	564 - 570	564	Similar weak, zonal or southwesterly flow to missing day
12	6	11	6	12	564	576	576 - 582	Similar weak, zonal flow to missing day
12	9	8	9	10	582	588	588	Since 9/9 is missing, use 9/10 because of similar weak, zonal flow
12	9	9	9	10	588	588	582	Similar weak, zonal flow to missing day
12	9	14	9	15	582 - 588	588	588	Similar weak, zonal flow to missing day
12	10	17	10	18	570 - 576	552 - 558	564 - 570	Similar strong, northwesterly flow to missing day; on backside of same low pressure
13	1	19	1	20	564 - 570	564 - 570	564 - 570	Similar strong, northwesterly flow to missing day
13	2	28	2	27	552	552 - 558	564	Similar weak, northwesterly flow to missing day
14	2	5	2	7	540	540	540	Since 2/6 is missing, use 2/7 because of similar zonal flow
14	2	6	2	7	540	540	540- 546	Similar zonal flow to missing day

Selected sounding for missing day

Missing sounding data for this day (12Z)

<sup>1</sup> Corrected stack coordinates provided to WDEQ-AQD by SWRC on 8/5/15.

<sup>2</sup> Stack height is the actual stack height used in permit action MD-12620.

<sup>3</sup> The calculated 3-year average effective release height and diameter during upset conditions were used in the AERMOD input file for the stack height and diameter for the North Flare. Emissions represent normal operations from permit action MD-15648.

<sup>4</sup> The Bypass stack was not modeled in permit action MD-15648. The stack height and diameter were provided to WDEQ-AQD by SWRC on 8/5/15. The emission rate, stack temp, and velocity are zero on this table, which was used for normal operations (this EU does not emit SO2 during normal operations). The emission rates, stack temps, and velocities during upset conditions are provided in the AERMOD hourly emission file.

<sup>5</sup> The calculated 3-year average effective release height and diameter during upset conditions were used in the AERMOD input file for the stack height and diameter for the South Flare. Normal operation emissions were modeled as 0 g/s in permit action MD-12620; The South Flare was not modeled in permit action MD-15648.

		Excess	Emission Source to Model/
Date	General Description	Emissions	Hours Emissions Occurred
5/20/12	Tail Gas Incident: Excess SO2 tail gas emissions on #4	1018.2 lbs	#4 SRU stack
	TGTU.	SO2	0706 – 1918
			Hours contributing to >500 lbs: 1000, 1400 - 1900
			(see RCFA report hourly amounts)
6/10/12	Tail Gas Incident: Excess SO2 tail gas emissions	2121.9 lbs	#3 SRU stack
	resulted when #3 TGTU shutdown.	SO2	0322 – 1211
			Hours contributing to >500 lbs: 0300 – 1200 (see
			RCFA report hourly amounts)
6/28/12	Acid Gas Flaring Incident: Hydrocarbon in the feed to	706.5 lbs	South Flare
	#3 and #4 ARUs upset their operation and vaporized	SO2	0251 – 0259
	into the Acid Gas feed to #3 and #4 SRUs. This		Hours contributing to >500 lbs: not provided, but
	pressured up and shutdown both SRUs.		assume it's hour 0200; however, hours 0400 – 0600
			listed as "Acid Gas Event" in 6/28/12 Tail Gas
			Incident Report described below
6/28/12	Tail Gas Incident: Excess SO2 tail gas emissions on #4	787.9 lbs	#4 SRU stack
	TGTU.	SO2	1158 – 2308
			Hours contributing to >500 lbs: 1100 – 1400, and
			2100 – 2200 (see RCFA report hourly amounts);
			Total listed (and verified from hourly lbs) = 786.9 lbs
7/24/12	Tail Gas Incident: Excess SO2 tail gas emissions	916.0 lbs	#3 SRU stack
	resulted when #3 TGTU shutdown.	SO2	1442 – 1806
			Hours contributing to >500 lbs: 1500 – 1800 (see
			RCFA report hourly amounts).
7/24/12	EPCRA/CERCLA release: PLC problem on the #3	123 lbs H2S	#3 SRU stack
	SRU/TGTU and TTO (this report included at the end of		Started at 1442 and lasted 3.3 hours (see SO2
	the 7/24/12 Tail Gas report listed above).		emissions in Tail Gas report listed above)
7/25/12	Tail Gas Incident: Excess SO2 tail gas emissions	692.1 lbs	#3 SRU stack
	resulted when #3 TGTU shutdown.	SO2	1345 – 1706
			Hours contributing to >500 lbs: 1400 – 1700 (see
			RCFA report hourly amounts)
12/6/12	EPCRA/CERCLA release: Hydrocarbon carryover to	129 lbs H2S	#3 and #4 SRU/TGTU
	the amine units resulting in the #3 and #4 SRU/TGTU		Started at 1432 and lasted 2.4 hours (see SO2
	and TTO units to be upset.		emissions in Tail Gas report listed below)

		Excess	Emission Source to Model/
Date	General Description	Emissions	Hours Emissions Occurred
12/6/12	Tail Gas Incident: Exceeded 500 lb excess SO2 tail	1710.8 lbs	#3 and #4 SRU stacks
	gas emissions during #3 and #4 SRU upset.	SO2	1432 – 1653 for #3 SRU
			1357 – 1555 for #4 SRU
			Hours contributing to >500 lbs:
			#3 SRU: 1400 – 1600
			#4 SRU: 1400 – 1600
			(see RCFA report hourly amounts)
12/9/12	Tail Gas Incident: Excess SO2 tail gas emissions on #3	5354.9 lbs	#3 and #4 SRU stacks
	and #4 TGTU.	SO2	1350 – 1859 for #3 SRU
			1358 – 2338 for #4 SRU
			Hours contributing to >500 lbs:
			#3 SRU: 1400 – 1800)
			#4 SRU: 1400 – 2300
			(see RCFA report hourly amounts)
1/15/13	EPCRA/CERCLA release: Hydrocarbon carryover to	134 lbs H2S	#3 and #4 SRU/TGTU
	the amine units resulting in the #3 and #4 SRU/TGTU		Started at 1136 and lasted 2.2 hours (see SO2
	and TTO units to be upset.		emissions in Tail Gas report listed below)
1/15/13	Tail Gas Incident: Excess SO2 tail gas emissions on #3	1279.6 lbs	#3 and #4 SRU stacks
	and #4 TGTU.	SO2	1136 – 1346 for #3 SRU
			1139 – 1313 for #4 SRU
			Hours contributing to >500 lbs:
			#3 SRU: 0300 – 0600, 1100 - 1400
			#4 SRU: 1100 – 1300
			(see RCFA report hourly amounts)
5/8/13	Tail Gas Incident: Excess SO2 tail gas emissions from	869.7 lbs	#1 TGTU bypass stack
	the #2 SRU bypass incinerator caused by a power	SO2	1839 – 2053
	failure.		Hours contributing to >500 lbs: 1800 – 2000
			(see RCFA report hourly amounts)
5/22/13	Tail Gas Incident: Excess SO2 tail gas emissions from	1723.9 lbs	#1 TGTU bypass stack
	the #2 SRU bypass incinerator.	SO2	0700 – 1222
			Hours contributing to >500 lbs: 0700 – 1300
			(see RCFA report hourly amounts)
5/23/13	Tail Gas Incident: Excess SO2 tail gas emissions from	1183.5 lbs	#3 TGTU stack
	the #3 TGTU tripping offline.	SO2	1035 – 1415
			Hours contributing to >500 lbs: 1000 – 1400
			(see RCFA report hourly amounts)

		Excess	Emission Source to Model/
Date	General Description	Emissions	Hours Emissions Occurred
8/2/13	Tail Gas Incident: Exceeded 500 lb excess SO2 tail	910.9 lbs	#3 SRU stack
	gas emissions during cold-bed start up of #3 SRU.	SO2	1700 – 2131
			Hours contributing to >500 lbs: 1700 – 2300
			(see RCFA report hourly amounts)
8/31/13	Tail Gas Incident: Excess SO2 tail gas emissions from	814.0 lbs	#3 TGTU stack
	the #3 TGTU tripping offline.	SO2	1609 – 2013
			Hours contributing to >500 lbs: 1600 – 2000
			(see RCFA report hourly amounts)
9/4/13	Tail Gas Incident: Excess SO2 tail gas emissions from	648.6 lbs	#4 TGTU stack
	the #4 TGTU tripping offline.	SO2	1554 – 1759
			Hours contributing to >500 lbs: 1600 – 1700
			(see RCFA report hourly amounts)
10/2/13	Tail Gas Incident: Excess sulfur dioxide emissions from	846.4 lbs	#3 and #4 SRU stacks
	#3 and #4 TGTUs.	SO2	0203 – 1018 for #3 TGTU
			0648 – 0731 for #4 TGTU
			Hours contributing to >500 lbs:
			#3 SRU: 0400, 0800 – 1000)
			#4 SRU: 0700
			(see RCFA report hourly amounts)
10/8/13	Tail Gas Incident: Excess SO2 tail gas emissions due	1611.9 lbs	#4 SRU stack
	to #4 SRU/#4TGTU shutdown.	SO2	1615 – 2303
			Hours contributing to >500 lbs: 1500 – 2300
			(see RCFA report hourly amounts)
11/3/13	Tail Gas Incident: Excess SO2 tail gas emissions due	818.1 lbs	#4 TGTU stack
	to #4TGTU shutdown.	SO2	0058 – 0259
			Hours contributing to >500 lbs: 0100 – 0300
			(see RCFA report hourly amounts)
11/15/13	Tail Gas Incident: Excess SO2 tail gas emissions due	2000.0 lbs	#4 TGTU stack
	to #4TGTU shutdown.	SO2	1233 – 2245
			Hours contributing to >500 lbs: 1200 – 1700, 2000 -
			2300
			(see RCFA report hourly amounts)

		Excess	Emission Source to Model/
Date	General Description	Emissions	Hours Emissions Occurred
12/28/13	Tail Gas Incident: Excess SO2 tail gas emissions due	790.8 lbs	#4 TGTU stack
	to #4TGTU shutdown.	SO2	1103 – 1925
			Hours contributing to >500 lbs: 1100 – 1300, 1800 -
			1900
			(see RCFA report hourly amounts)
12/29/13	Tail Gas Incident: Excess SO2 tail gas emissions due	985.7 lbs	#4 TGTU stack
	to #4TGTU shutdown.	SO2	1534 – 1817
			Hours contributing to >500 lbs: 1500 – 1900
			(see RCFA report hourly amounts)
12/30/13	Tail Gas Incident: Excess SO2 tail gas emissions due	665.5 lbs	#4 TGTU stack
	to #4TGTU shutdown.	SO2	0956 – 1817
			Hours contributing to >500 lbs: 1000 – 1100, 1600 -
			1700
			(see RCFA report hourly amounts)
1/3/14	Tail Gas Incident: Excess SO2 tail gas emissions due	1075.0 lbs	#4 TGTU stack
	to #4 TGTU shutdown.	SO2	0635 - 1234
			Hours contributing to >500 lbs: 0600 – 0700, 0900 –

<sup>1</sup> The allocations of	emissions to the flare	e listed in this column	was based	on a review	<i>w</i> of eac	h RCF	A rep	ort. If t	he RCFA	repo	t was r	ot clear on wh	ich flare emitted, then the	ollowing default as	ssumptions were	made	]	max VERT	FLAR values =>	59.10	4.50
based on input fr	om SWRC (communic	cation with Glenn Spar	ngler of the	AQD on 9/	9/15):												÷	min VERT	FLAR values =>	47.20	1.88
For years 2012 a	nd 2013, and through	January 31, 2014, the	South Fla	re (VERTFI	_AR) wa	is the p	orefer	red flar	e for the	efine	y. Star	ting in Februar	y 2014, the preferred flare	vas changed to be	e the North Flare	(COKEFLAR).	-	avg VERT	FLAR values =>	52.36	3.01

For years 2012 and 2013, and through January 31, 2014, the South Flare (VERTFLAR) was the preferred flare for the refinery. Starting in February 2014, the preferred flare was changed to be the North Flare (COKEFLAR). <sup>2</sup> The emission rate is the average emission rate from the RFCA. However, if a flaring event lasted less than one hour, then the reported lb/event value was used for the hour in which the emissions occurred.

For years 2012 and 2013, and through January 31, 2014, the South Flare (VERTFLAR) was the preferred flare for the refinery. Starting in February 2014, the preferred flare was changed to be the North Flare (COKEFLAR). <sup>2</sup> The emission rate is the average emission rate from the RFCA. However, if a flaring event lasted less than one hour, then the reported lb/event value was used for the hour in which the emissions occurred.

<sup>1</sup> The allocations of emissions to the flare listed in this column was based on a review of each RCFA report. If the RCFA report was not clear on which flare emitted, then the following default assumptions were made based on input from SWRC (communication with Glenn Spangler of the AQD on 9/9/15):

For years 2012 and 2013, and through January 31, 2014, the South Flare (VERTFLAR) was the preferred flare for the refinery. Starting in February 2014, the preferred flare was changed to be the North Flare (COKEFLAR). <sup>2</sup> The emission rate is the average emission rate from the RFCA. However, if a flaring event lasted less than one hour, then the reported lb/event value was used for the hour in which the emissions occurred.

<sup>3</sup> GRNDFLAR (Emergency Ground Flare) was modeled as a volume source; therefore heat release rate, and effective release height/diameter are not applicable.

## Technical Support Document for Carbon County, Wyoming 1-hour SO<sub>2</sub> Designation

This technical support document is attached in support of the evaluation performed to determine an appropriate designation for Carbon County, Wyoming in response to Acting Assistant Administrator Janet McCabe's letter dated March 20, 2015 to Wyoming Department of Environmental Quality (WDEQ) Director Todd Parfitt.

These evaluations included a detailed review of the SO<sub>2</sub> air quality measurements during the times when the value of the 2010 SO<sub>2</sub> National Ambient Air Quality Standard (NAAQS) was exceeded, including data submissions to the EPA and WDEQ Air Quality Divisions (AQD) as required by the May 8, 2008 Consent Decree between the United States of America and SWRC, and other reports submitted by Sinclair Wyoming Refining Company (SWRC) to the WDEQ-AQD regarding ambient air quality monitoring. The WDEQ-AQD has also conducted a refined air dispersion modeling evaluation to inform the designation recommendation. Each of these evaluations is summarized in this letter.

## SO2 Air Quality Monitoring Data Evaluation

SWRC operates a SO<sub>2</sub> air quality monitor located approximately 650 meters northeast of the main SWRC emission units, as shown in Figure 1-1 in Attachment 1. Table 1-1 in Attachment 1 shows the hours when the value of the 2010 SO<sub>2</sub> NAAQS of 75 parts per billion (ppb) was exceeded. The calculated 1-hour SO<sub>2</sub> design value from this monitor for the period from 2012 to 2014 is 123 ppb.

Table 1-1 provides the wind speed and wind direction (the direction from which the wind is blowing) for each exceedance hour, along with a brief summary of the causes for the exceedances according to SWRC. The WDEQ-AQD has evaluated these exceedance hours in detail. Based on the wind flow during each monitored exceedance, the winds were blowing from the southwesterly direction with the SO<sub>2</sub> monitor directly downwind of SWRC emission units. As reported by SWRC, various emission units were upset during the monitored exceedances. Additionally, a detailed review of ambient SO<sub>2</sub> monitoring data collected by the WDEQ-AQD's mobile air monitoring station located in the Town of Sinclair (AQS ID number 56-007-1000) and review of other permitted stationary sources in the region, showed no other significant nearby sources of SO<sub>2</sub> emissions in the vicinity of SWRC that could have significantly contributed to the monitored exceedances. Therefore, the WDEQ-AQD has concluded that the elevated SO<sub>2</sub> air concentrations were clearly attributed to the SWRC upset conditions listed in Table 1-1.

The WDEQ-AQD also reviewed the location of this monitor as part of the evaluation of the data. It is evident that this monitor is located outside of SWRC's currently permitted modeling ambient boundary shown in Figure 1-1; however, it is also located within an existing fence that restricts public access to the area where the monitor is located. Because the monitor is located within an existing fence, the WDEQ-AQD cannot rely solely on the SO<sub>2</sub> concentrations measured at the SWRC SO<sub>2</sub> air quality monitor in making its designation recommendation for this area.

## Refined Air Dispersion Modeling Evaluation

In an effort to further assess the air quality surrounding the SWRC stationary source, the WDEQ-AQD conducted a refined air dispersion modeling evaluation to inform its designation recommendation. The purpose of the modeling evaluation was to use all available information and data available to the WDEQ-AQD to determine if a modeled violation of the 1-hour SO<sub>2</sub> NAAQS would be identified in the vicinity of the SWRC stationary source and SO<sub>2</sub> air quality monitor.

The modeling was conducted in accordance with the EPA's December 2013 SO<sub>2</sub> NAAQS Designations Modeling Technical Assistance Document (Modeling TAD), as referenced in the final Data Requirements Rule<sup>1</sup> (DRR), as well as 40 CFR 51, Appendix W (EPA's Modeling Guideline). The Modeling TAD provides recommendations on several aspects of the 1-hour SO<sub>2</sub> dispersion modeling approach for designation purposes including the use of hourly actual emissions, source characterization, meteorological data, model selection, and background concentrations. The latest version of the EPA's AERMOD modeling system (Version 15181 and associated pre-processors) was used in its regulatory default mode.

The WDEQ-AQD developed the model inputs using several sources of information and data to capture the SWRC operating conditions during the period from 2012 to 2014. The primary sources of hourly SO<sub>2</sub> emissions data used in the modeling were from SWRC's continuous emission monitoring systems (CEMS) where available, information about upset events obtained from various submittals required by the May 8, 2008 Consent Decree, existing Federally-enforceable permit limits, and other Federally-required reporting data. Other inputs developed by the WDEQ-AQD included direction-specific downwash parameters for SWRC emission units, appropriately located receptors, concurrent meteorological data collected at SWRC for the period from 2012 to 2014, nearby permitted stationary sources, and temporally and seasonally varying background SO<sub>2</sub> concentrations.

<sup>&</sup>lt;sup>1</sup> 80 FR 51054.

The results of the modeling analysis indicated that there were no modeled violations of the 1-hour SO<sub>2</sub> NAAQS within the full receptor grid developed for areas on and outside of the SWRC permitted modeling ambient air boundary. The maximum modeled 1-hour SO<sub>2</sub> design value concentration predicted by AERMOD was 62.1 ppb [162.6 micrograms per cubic meter ( $\mu$ g/m<sup>3</sup>)]. Isopleth maps of the modeled 1-hour SO<sub>2</sub> design value concentrations are provided in Figures 2-1 through 2-3 in Attachment 2. Review of Figures 2-1 and 2-2 indicate that the maximum modeled design values occur in the vicinity of SWRC with no elevated design value impacts in the near or far-field of the modeling domain. Figure 2-3 provides a near-field isopleth map of the modeled 1-hour SO<sub>2</sub> design value concentrations in the immediate vicinity of the SWRC stationary source and SO<sub>2</sub> air quality monitor. This figure shows a strong SO<sub>2</sub> concentration gradient to the north and northeast of SWRC emission units, and in the area around the SO<sub>2</sub> air quality monitor.

Based on the WDEQ-AQD's refined dispersion modeling evaluation results, the WDEQ-AQD determined that the available modeling evaluations were inconclusive for use in making a designation recommendation for the 1-hour SO<sub>2</sub> NAAQS.

The WDEQ-AQD's detailed air dispersion modeling report is included in Attachment 3, which provides the details of the model inputs, model options, and results of the evaluation.
