Commercial and Recreational Fisheries Assessment

Status of Impacts to Fisheries

There are two basic fisheries, the nearshore coral reef fisheries, and the pelagic or offshore fisheries. The offshore fishery is dependent upon use of long lines, ranges far offshore (up to 1,500 miles) and is focused on the valuable pelagic species such as tuna. The nearshore fishery (excluding the Northwest Hawaiian Islands lobster fishery) was worth just 4 percent of the pelagic catch (Dollar, 1993). Catch records are maintained by the state for all licensed commercial fishermen who must report their catches monthly.

Marine recreational fishermen are not licensed, and catch records are not available. The commercial catch recorded near the Honouliuli outfall is recorded as being within one of a series of statistical areas referred to as fishing blocks by the State of Hawaii. The locations and designations of these blocks are shown on Figure G-2-1. Fishing blocks 400 to 409 encompass the nearshore regions around Oahu (Figure G-2-1), while the offshore areas are designated for blocks 420 to 429. The Honouliuli outfall discharge is in the block designated 401. Block 401 extends from just beyond the reef, about 2 nautical miles from shore, while the outer boundary of the offshore areas extends a distance of about 20 nautical miles.

The shoreline area is the region where impacts would be expected to occur. Fishing block 401 extends from the Honolulu Airport to Barbers Point and was estimated to be used by an estimated 9.6 percent of the inshore fisherman. The offshore block, 421, was used by an estimated 8.4 percent of fisherman (Hawaii Department of Land and Natural Resources, 1979).

Catch records for block 401 and the two blocks on either side (400 and 402) have been compiled for comparative purposes and are shown in Tables G-2-1, G-2-2, and G-2-3. The data for block 401 is shown in Table G-2-2.

Evaluations and comparisons of the data are done as part of the Annual Assessment prepared by the city. To date, no significant findings regarding the potential effects of the Honouliuli discharge have been noted. One interesting analysis was done by Dr. Richard Brock for the 1993 evidentiary hearing on the Honouliuli NPDES permit (Brock, 1993). This analysis included data for the period prior to the construction of the Honouliuli outfall (1970-1971), data for the period when the outfall became operational (1981-1982), and data representing more recent conditions (1990-1991). Dr. Brock's analysis of commercial fisheries for the periods 1971-1972, 1981-1982 and 1991-1992 included statistics for block 401 and compared these with statewide catch records. His analysis included a comparison of the dollar value of the catch and the number of licensed fisherman statewide for the three time frames. His analysis was done to put the historical trends in perspective and to address the question of whether the fishery changed after the outfall was constructed and made operational. His analysis is summarized in Table G-2-4. He noted from this analysis that:

Area Code	Inshore Areas	Percentage of Total Inshore Fishermen	Area Code	Offshore Areas	Percentage of Total Offshore Fishermen
403	Mali Point to Keena Point	14.6	420	Diamond Head to Honolulu Airport	22.0
400	Diamond Head to Honolulu Airport	13.3	423	Mali Point to Keena Point	18.8
407	Kaawa Point to Mokapu Pen.	12.3	427	Kaawa to Mokapu Pen.	18.2
409	Makapuu Point to Diamond Head	10.6	429	Makapuu Point to Diamond Head	8.7
408	Mokapu Pen to Makapuu Point	9.7	421	Honolulu Airport to Barbers Point	8.4
401	Honolulu Airport to Barbers Point	9.6	426	Laiie to Kaawa	7.0
404	Kaena Point to Puamalu	8.6	428	Makapu Pen to Makapuu Point	6.3
405	Puamalu to Laiie	8.0	424	Kaena Point to Puamalu	4.9
406	Laiie to Kaawa	7.9	425	Puamalu to Laiie	3.4
402	Barbers Point to Mali Point	5.4	422	Barbers Point to Mali Point	2.3

- 1) The catches made in this square are trivial relative to those statewide accounting for about 0.3 to 0.8 percent of the totals for the state.
- 2) The annual catch of 0.7g/m² was very low in terms of productivity, similar in 1971 and 1991, and that this area was not significant state fishing waters.
- 3) Changes noted in the fishery are not significant, and the variation is probably related to the effort expended and reported rather than from changes in abundance in species.
- 4) There are no significant shellfish resources harvested in the area because they are not present.

Brock (1993) concluded that: "The commercial fisheries data suggest that the coral reef fisheries in the vicinity of the Honouliuli discharge have not been significantly different from the time preceding outfall construction, and have not significantly changed since that outfall became operational."

The inshore fishes grouping shown in Table G-2-4 includes reef fishes as well as coastal pelagic species such as akule, *Selar crumenophthalmus* and the opelu, *Decapterus macarellus*, which represent some of the most desirable species and are those for which bioaccumulation analyses are done.

Analysis of the information presented in Tables G-2-1 through G-2-3 is summarized and shown graphically on Figure G-2-2. As shown, block 401 commercial catch records show that a very stable and sustained fishery exists at between 60,000 and 80,000 pounds per year since 1989. From such data there is no evidence of any adverse impact from the Honouliuli outfall. Most of the catch is accounted for by akule as shown on Figure G-2-3. Again the fishery has been thriving since 1988. Catch records for ta'ape are presented in Figure G-2-4. These records show no decline in the fishery over the study period. The other species are of interest because they are caught for bioaccumulation analyses. This species accounts for between approximately 200 to 4,600 pounds per year and does not represent a significant portion of the commercial catch.
